Abstract

We initiate the study of constructions for indistinguishability obfuscation for quantum circuits. In particular, we construct an indistinguishability obfuscator that takes as input a quantum circuit, and outputs a quantum state and a quantum circuit, which together can be used to evaluate the original quantum circuit, on any quantum input. In our construction, the size of the output of the obfuscator is exponential in the number of non-Clifford gates, which means that the construction is efficient as long as the number of non-Clifford gates is logarithmic.

1 Introduction

Indistinguishability obfuscation $(i\mathcal{O})$ was first proposed by Barak, Goldreich, Impagliazzo, Rudich, Sahai, Vadhan and Yang [?]. Among other things, it has been shown to enable digital signatures, public key encryption [?], multiparty key agreement, broadcast encryption [?], fully homomorphic encryption [?] and zero knowledge [?] etc. In this work, we continue the study of computational indistinguishable obfuscation in the quantum world. The main contribution of this paper is to provide a new definition of quantum indistinguishability obfuscation $Qi\mathcal{O}$ and show how to construct a $Qi\mathcal{O}$ for certain families of quantum circuits. The first construction is based on the canonical representation of Clifford circuits [?], while the second construction is based on the principle of gate teleportation [?]. The two constructions present different advantages: the technique using the canonical form is straightforward and does not require any computational assumption. Moreover, the obfuscated circuits are classical, and hence can be easily communicated, stored, used and copied. In contrast, the gate-teleportation scheme requires the assumption of quantum-secure classical $i\mathcal{O}$ for a certain family of functions (section 2.3) and the obfuscated circuits are quantum. While this presents a technological challenge to communication, storage and also usage, this methodology

allow us to obfuscate a more general set of quantum circuit than the canonical base contruction. Moreover the gate-teleportation methodology could also enable a new functionality related to the *unclonability* of quantum states. (Anne need to fill in)

1.1 Related Work

The quantum obfuscation was first studied in [], where a new notion called (G, Γ) -indistinguishability obfuscation was proposed. Where G is a set of gates and Γ is a set of relations satisfied by the elements of G. In this notion any two circuits over the set of gates G are perfectly indistinguishable if they differ by some sequence of applications of the relations in Γ . One of the motivations of their work was to provide a weaker definition of perfectly indistinguishable obfuscation, which is shown to be impossible under certain complexity-theoretic assumptions []. However, (G, Γ) -indistinguishability obfuscation appears to be incomparable with the computational indistinguishability obfuscation [], which is the topic of this paper.

The quantum obfuscation is studied more rigorously in [], where the following notions of quantum obfuscation are defined.

- 1. Quantum black-box obfuscation.
- 2. Quantum information-theoretic black-box obfuscation.
- 3. Quantum indistinguishability obfuscation (perfect, statistical, computational).
- 4. Quantum Best-Possible obfuscation (perfect, statistical, computational).

The main contribution of their work was to extend the classical impossibility results to the quantum settings such as a generic transformation of quantum circuits into black-box-obfuscated quantum circuits is impossible [], statistical indistinguishability obfuscation is impossible, up to an unlikely complexity-theoretic collapse []. However, no concrete instantiation was provided in their paper for any of type quantum obfuscations. They also discussed a number of applications of quantum black-box obfuscation such as CPA-secure quantum encryption, quantum fully-homomorphic encryption, and public-key quantum money, however it is not clear what impact these impossibility results have on these applications. They also showed that an existence of a computational quantum indistinguishability obfuscation would imply a witness encryption scheme for all languages in QMA [].

In this work we define a new definition of computational quantum obfuscation $Qi\mathcal{O}$ and provide two concrete instantiation of it. The first instantiation is based on the work of Aronson and Gottesman [?], In this paper, an efficient algorithm to compute a canonical form of any Clifford circuit was describe. However, the canonical form was not guaranteed to be unique, so we slightly modified their algorithm so that it always outputs a unique canonical form for any Clifford circuit. The second instantiation is based on gate-teleportation [] and assume an existence of a quantum-secure classical $i\mathcal{O}$ for certain class of functions (section 2.3). Using this technique we can obfuscate any n-qubit quantum circuit as far as the number of T gates are in $O(\log(n))$.

2 Preliminaries

2.1 Basic Classical Cryptographic Notions

Let \mathbb{N} be the set of positive integers. For $n \in \mathbb{N}$, we set $[n] = \{1, \dots, n\}$. We denote the set of all binary strings of length n by $\{0,1\}^n$. An element $s \in \{0,1\}^n$ is called a bitstring, and |s| = n denotes its length. We reserve the notation 0^n (resp., 1^n) to denote the n-bit string with all zeroes (resp., all ones). We denote an arbitrary polynomial from the set \mathbb{N} to \mathbb{N} by poly().

A function negl: $\mathbb{N} \to \mathbb{R}^+ \cup \{0\}$ is negligible if for every positive polynomial p(n) there exists a positive integer n_0 such that for all $n > n_0$, negl(n) < 1/p(n). A typical use of negligible functions is to indicate that the probability of success of some algorithm is too small to be amplified to a constant by a feasible (*i.e.*, polynomial) number of repetitions. Given two bit strings x and y of equal length, we denote their bitwise XOR by $x \oplus y$.

Classical Circuits and Algorithms

For $n, m \in \mathbb{N}$ let $f : \{0, 1\}^n \to \{0, 1\}^m$ be a function. We say a circuit C computes f if for every $s \in \{0, 1\}^n$, C(s) = f(s). We define the size of a circuit C as the number of gates in it and is denoted by |C|. A set of gates for classical computation are universal if, for all $n, m \in \mathbb{N}$, and for every function $f : \{0, 1\}^n \to \{0, 1\}^m$ a circuit can be constructed for computing f using only gates from that set. It is a well known fact that $\{AND, OR, NOT\}$ is a set of universal gates for classical circuits. A family of circuits $\mathcal{F} = \{C_n \mid n \in \mathbb{N}\}$, one for each input size $n \in \mathbb{N}$ is called uniform if there exists a deterministic Turing machine M, such that

- For each $n \in \mathbb{N}$, M outputs a description of $C_n \in \mathcal{F}$ on input 1^n .
- For each $n \in \mathbb{N}$, M runs in poly(n).

Definition 1. (Quantum Secure Indistinguishability Obfuscation $i\mathcal{O}$) A probabilistic polynomial-time algorithm is a quantum secure computational indistinguishability obfuscator $i\mathcal{O}$, for a class of circuits \mathcal{C} , if the following conditions hold:

1. Functionality: For any circuit $C \in \mathcal{C}$, and for all inputs x

$$i\mathcal{O}(C)(x) = C(x).$$

2. Polynomial Slowdown: For every $C \in \mathcal{C}$, $|i\mathcal{O}(C)| \in poly(|C|)$.

¹ANNE: Is there an advantage in using quantum states to obfuscate programs? I would suspect that one big advantage would be unclonable programs (they cannot be copied). Is this too ambitious to look at? What does it even mean to have unclonable programs? (this links with work that I am currently doing with Sébastien Lord, a PhD student).

3. Indistinguishability: For any two circuits $C_0, C_1 \in \mathcal{C}$, of the same size that compute the same function and for every polynomial time quantum distinguisher \mathcal{D}_q , there exists a negligible function negl such that:

$$\left|\Pr[\mathcal{D}_q(i\mathcal{O}(C_0)) = 1] - \Pr[\mathcal{D}_q(i\mathcal{O}(C_1)) = 1]\right| \le \operatorname{negl}(|C_0|).$$

2.2 Basic Quantum Notions

[?] Given an *n*-bit string x, the corresponding quantum-computational n-qubit basis state is denoted $|x\rangle$. The 2^n -dimensional Hilbert space spanned by n-qubit basis states is denoted

$$\mathcal{H}_n := \mathbf{span} \{ |x\rangle : x \in \{0,1\}^n \}$$
.

We denote by $\mathcal{D}(\mathcal{H}_n)$ the set of density operators (i.e., valid quantum states) on \mathcal{H}_n . These are linear operators on $\mathcal{D}(\mathcal{H}_n)$ which are positive-semidefinite and have trace equal to 1. When considering different physical subsystems, we will denote them with uppercase Latin letters; when a Hilbert space corresponds to a subsystem, we will place the subsystem label in the subscript. For instance, if $F \cup G \cup H = [n]$ then $\mathcal{H}_n = \mathcal{H}_F \otimes \mathcal{H}_G \otimes \mathcal{H}_H$. Sometimes we will write explicitly the subsystems a state belongs to as subscripts; this will be useful when considering, e.g., the reduced state on some of the subspaces. For example, we will sometimes express the statement $\rho \in \mathcal{D}(\mathcal{H}_F \otimes \mathcal{H}_G \otimes \mathcal{H}_H)$ simply by calling the state ρ_{FGH} ; in that case, the state obtained by tracing out the subsystem H will be denoted ρ_{FG} .

Given $\rho, \sigma \in \mathcal{D}(\mathcal{H})$, the trace distance between ρ and σ is given by half the trace norm $\|\rho - \sigma\|_1$ of their difference. When ρ and σ are classical probability distributions, the trace distance reduces to the total variation distance. Physically realizable maps from a state space $\mathcal{D}(\mathcal{H})$ to another state space $\mathcal{D}(\mathcal{H}')$ are called admissible—these are the completely positive trace-preserving (CPTP) maps. For the purpose of distinguishability via input/output operations, the appropriate norm for CPTP maps is the diamond norm, denoted $\|\cdot\|_{\diamond}$. The set of admissible maps coincides with the set of all maps realizable by composing (i.) addition of ancillas, (ii.) unitary evolutions, (iii.) measurements in the computational basis, and (iv.) tracing out subspaces. We remark that unitaries $U \in U(\mathcal{H}_n)$ act on $\mathcal{D}(\mathcal{H}_n)$ by conjugation: $\rho \mapsto U\rho U^{\dagger}$. The identity operator $\mathbb{1}_n \in U(\mathcal{H}_n)$ is thus both a valid map, and (when normalized by 2^{-n}) a valid state in $\mathcal{D}(\mathcal{H}_n)$ —corresponding to the classical uniform distribution.

Quantum Gates

Recall the single-qubit Pauli operators defined as:

$$\mathsf{I} = \left[\begin{array}{cc} 1 & 0 \\ 0 & 1 \end{array} \right] \,, \qquad \mathsf{X} = \left[\begin{array}{cc} 0 & 1 \\ 1 & 0 \end{array} \right] \,, \qquad \mathsf{Y} = \left[\begin{array}{cc} 0 & -i \\ -i & 0 \end{array} \right] \,, \qquad \mathsf{Z} = \left[\begin{array}{cc} 1 & 0 \\ 0 & -1 \end{array} \right] \,.$$

The Pauli operators are Hermitian and unitary quantum gates, i.e. $P^{\dagger} = P$ and $P^{\dagger}P = PP^{\dagger} = P^2 = I$ for all $P \in \{I, X, Y, Z\}$. It is easy to check that applying a uniformly random Pauli operator to any single-qubit density operator results in the maximally mixed state:

$$\frac{1}{4}\left(\rho + \mathsf{X}\rho\mathsf{X} + \mathsf{Y}\rho\mathsf{Y} + \mathsf{Z}\rho\mathsf{Z}\right) = \frac{\mathbb{1}_1}{2} \qquad \text{for all } \rho \in \mathcal{D}(\mathcal{H}_1)\,.$$

Since the Pauli operators are self-adjoint, we may implement the above map by choosing two bits s and t uniformly at random and then applying

$$\rho \mapsto \mathsf{X}^s \mathsf{Z}^t \rho \mathsf{Z}^t \mathsf{X}^s$$
.

To observers with no knowledge of s and t, the resulting state is information-theoretically indistinguishable from $\mathbb{1}_1/2$. Of course, if we know s and t, we can invert the above map and recover ρ completely.

The above map can be straightforwardly extended to the *n*-qubit case in order to obtain an elementary quantum encryption scheme called the quantum one-time pad. We first set $X_j = \mathbb{1}^{\otimes j-1} \otimes X \otimes \mathbb{1}^{\otimes n-j}$ and likewise for Y_j and Z_j . We define the *n*-qubit Pauli group \mathcal{P}_n to be the subgroup of $SU(\mathcal{H}_n)$ generated by $\{X_j, Y_j, Z_j : j = 1, ..., n\}$. Note that Hermiticity is inherited from the single-qubit case, i.e. $P^{\dagger} = P$ for every $P \in \mathcal{P}_n$.

Definition 2. Clifford Group: The set of gates {X,Z,P,CNOT,H} applied to arbitrary wires (redundantly) generates the Clifford group, where

$$X = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \quad Z = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}, \quad P = \begin{bmatrix} 1 & 0 \\ 0 & i \end{bmatrix}, \quad H = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}, \quad and \quad CNOT = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix}.$$

We note the following relations between these gates:

$$XZ = -ZX$$
, $T^2 = P$, $P^2 = Z$, $HXH = Z$, $TP = PT$, $PZ = ZP$.

Also, for any $a, b \in \{0, 1\}$ we have $\mathsf{HX}^b \mathsf{Z}^a = \mathsf{X}^a \mathsf{Z}^b \mathsf{H}$

Quantum Circuits and Algorithm

For $n \in \mathbb{N}$, the set of all $n \times n$ unitary matrix is denoted by $O(n, \mathbb{C}) = \{U \in \mathbb{C}^{n \times n} \mid U \cdot U^{\dagger} = \mathbf{I}\}$. We say a quantum circuit C_q computes $U \in O(n, \mathbb{C})$ if for every quantum state $|\psi\rangle \in Qubit(n)$,

$$U(|\psi\rangle) = C_q(|\psi\rangle),$$

where Qubit(n) denote the set of all n-qubit states.

A quantum circuit that computes unitary matrix is called a reversible quantum circuit, i.e it always possible to uniquely recover the input, given the output. A set of gates are said to be universal if, for any a unitary matrix U a quantum circuit can be constructed for computing U using only gates from that set. It is a well known fact that Clifford gates are not universal, but adding any non-Clifford gate, such as T, gives a universal set of gates. The

$$\mathsf{T} = \left[\begin{array}{cc} 1 & 0 \\ 0 & e^{i\pi/4} \end{array} \right],$$

A family of quantum circuit $C = \{C_n \in \mathbb{N} \mid \}$ one for each input size $n \in \mathbb{N}$ is called uniform if there exists a deterministic Turing machine M, such that

- For each $n \in \mathbb{N}$, M outputs a description of $C_n \in \mathcal{F}$ on input 1^n .
- For each $n \in \mathbb{N}$, M runs in poly(n).

All quantum operations are not unitary (reversible), nevertheless a general (possibly irreversible) quantum operation also called superoperator can efficiently simulated by a reversible quantum operations by adding ancilla states to the original system, then perform a unitary operation on the joint system, and then tracing out Tr some subsystem []. More precisely, this can be described as the map:

$$\rho_{in} \xrightarrow{\text{superoperator}} \rho_{out} = Tr_B(U(\rho_{in} \otimes |00 \cdots 0\rangle\langle 00 \cdots 0|)U^{\dagger})$$

where $\rho_{in} \in \mathcal{H}_n$, is the original state and $|00\cdots 0\rangle$ is an ancilla state of dimension at most n^2 . A circuit that computes a general quantum operation is called a general quantum circuit. Therefore, general quantum circuit can refer to both reversible or irreversible circuits. A polynomial-time quantum algorithm is a uniform family of general quantum circuits.

Remark: From now we use the term quantum circuits to refer to reversible quantum circuits only and the term quantum algorithm is reserved for some family of general quantum circuits.

2.3 Correction and Update Functions for Clifford Circuits

For any Clifford gate $U \in \{X, Z, P, CNOT, H\}$ we define a correction function f_U that relates U and the Pauli's X and Z matrices in the following manner.

$$\begin{split} \mathsf{X}(\mathsf{X}^b\mathsf{Z}^a) &= (-1)^a(\mathsf{X}^b\mathsf{Z}^a)\mathsf{X}, \quad \text{where } f_\mathsf{H}(a,b) = (a,b), \text{ for any } a,b \in \{0,1\}. \\ \mathsf{Z}(\mathsf{X}^b\mathsf{Z}^a) &= (-1)^b(\mathsf{X}^b\mathsf{Z}^a)\mathsf{Z}, \quad \text{where } f_\mathsf{H}(a,b) = (a,b), \text{ for any } a,b \in \{0,1\}. \\ \mathsf{H}(\mathsf{X}^b\mathsf{Z}^a) &= (\mathsf{X}^a\mathsf{Z}^b)\mathsf{H}, \quad \text{where } f_\mathsf{H}(a,b) = (b,a), \text{ for any } a,b \in \{0,1\}. \\ \mathsf{P}(\mathsf{X}^b\mathsf{Z}^a) &= ((-i)^b\mathsf{X}^a\mathsf{Z}^{a\oplus b})\mathsf{P}, \quad \text{where } f_\mathsf{P}(a,b) = (a,a\oplus b), \text{ for any } a,b \in \{0,1\}. \\ \mathsf{CNOT}(\mathsf{X}^{b_1}\mathsf{Z}^{a_1} \otimes \mathsf{X}^{b_2}\mathsf{Z}^{a_2}) &= (\mathsf{X}^{b_1}\mathsf{Z}^{a_1\oplus a_2} \otimes \mathsf{X}^{b_1\oplus b_2}\mathsf{Z}^{a_2})\mathsf{CNOT}, \text{ where } f_\mathsf{CNOT}(a_1,b_1,a_2,b_2) = (a_1\oplus a_2,b_1,a_2,b_1\oplus b_2). \\ \mathsf{Similarly for any } n\text{-qubit Clifford Circuit}^2 \ \mathcal{C}_q \text{ we define an update function } F_{c_q}: \mathbb{F}_2^n \to \mathbb{F}_2^n, \text{ that} \end{split}$$

²A Clifford circuit is a quantum circuit in which every gate is from the Clifford group.

relates C_q and a unitary $(X^{\bigotimes_{i=1}^n b_i} \cdot Z^{\bigotimes_{i=1}^n a_i})$ in the following manner,

$$(\mathsf{X}^{\otimes_{i=1}^n b_i} \cdot \mathsf{Z}^{\otimes_{i=1}^n a_i})\mathcal{C}_q = \mathcal{C}_q(\mathsf{X}^{\otimes_{i=1}^n b_i'} \cdot \mathsf{X}^{\otimes_{i=1}^n a_i'})$$

where $a_i, b_i, a_i', b_i' \in \{0, 1\}$ for all integers $1 \le i \le n$ and $F_{c_q}(a_1, b_1, a_2, b_2, \dots a_n, b_n) = (a_1', b_1', \dots, a_n', b_n')$. The update function F_{c_q} is computed by the composition of the correction functions of the gates in the circuit C_q . For example consider a 2 qubit circuit Let $C_q = ((I \otimes H) \cdot (CNOT))$. The update function for this circuit is computed by first applying the f_H to the first two input bits and then f_{CNOT} to all four bits.

$$F_{C_q} = f_{\text{CNOT}} \circ f_{\text{H}}(a_1, b_1, a_2, b_2) = f_{\text{CNOT}}(b_1, a_1, a_2, b_2) = (b_1 \oplus a_2, a_1, a_2, a_1 \oplus b_2).$$

And we have

$$(\mathsf{X}^{b_1} \otimes \mathsf{X}^{b_2})(\mathsf{Z}^{a_1} \otimes \mathsf{Z}^{a_2})C_q = C_q(\mathsf{X}^{a_1} \otimes \mathsf{X}^{a_1 \oplus b_2})(\mathsf{Z}^{b_1 \oplus a_2} \otimes \mathsf{Z}^{a_2}).$$

Bell Basis

We denote the four Bell states as $|\beta_{00}\rangle$, $|\beta_{01}\rangle$, $|\beta_{10}\rangle$ and $|\beta_{11}\rangle$.

$$|\beta_{00}\rangle = \frac{1}{\sqrt{2}} (|00\rangle + |11\rangle)$$
 $|\beta_{01}\rangle = \frac{1}{\sqrt{2}} (|01\rangle + |10\rangle)$

$$|\beta_{10}\rangle = \frac{1}{\sqrt{2}} (|00\rangle - |11\rangle)$$
 $|\beta_{11}\rangle = \frac{1}{\sqrt{2}} (|01\rangle - |10\rangle)$

2.4 Gate Teleportation

Suppose we want to evaluate a single qubit gate $U \in \{X, Z, P, CNOT, H\}$ on some qubit $|\psi\rangle$. Then using gate teleportation we can compute $U(|\psi\rangle)$ as follows.

Algorithm 1 Gate Teleportation Protocol for Clifford Gates.

- 1. Prepare a 2 qubit Bell state $|\beta_{00}\rangle = \frac{|00\rangle + |11\rangle}{\sqrt{2}}$.
- 2. Write the joint system as

$$|\psi\rangle|\beta_{00}\rangle = \frac{1}{2}|\beta_{00}\rangle|\psi\rangle + \frac{1}{2}|\beta_{01}\rangle(\mathsf{X}(|\psi\rangle) + \frac{1}{2}|\beta_{10}\rangle(\mathsf{Z}(|\psi\rangle) + \frac{1}{2}|\beta_{11}\rangle(\mathsf{XZ}(|\psi\rangle). \tag{1}$$

Where β_{ij} , denotes the 2 qubit Bell basis.

3. Apply the Clifford gate U on the second qubit of the Bell state of the system 1.

$$\mathbb{I} \otimes \mathbb{I} \otimes U(|\psi\rangle|\beta_{00}\rangle) = \frac{1}{2}|\beta_{00}\rangle U(|\psi\rangle) + \frac{1}{2}|\beta_{01}\rangle U(\mathsf{X}(|\psi\rangle) + \frac{1}{2}|\beta_{10}\rangle U(\mathsf{Z}(|\psi\rangle) + \frac{1}{2}|\beta_{11}\rangle U(\mathsf{XZ}(|\psi\rangle). \tag{2}$$

4. Measure the first two qubits of the system 2 in the Bell basis and obtain the classical bits (a,b). The system now in the state

$$|\beta_{ab}\rangle \otimes U(\mathsf{X}^b\mathsf{Z}^a(|\psi\rangle)).$$
 (3)

- 5. Compute the correction function $f_U(a,b) = (a',b')$ associated with the gate U. (section 2.3).
- 6. Apply the correction unitary $Z^{a'}X^{b'}$ to the last qubit of the system 3

$$\mathbb{I} \otimes \mathbb{I} \otimes \mathbb{Z}^{a'} \mathsf{X}^{b'} \left(|\beta_{ab}\rangle \otimes U(\mathsf{X}^b \mathsf{Z}^a(|\psi\rangle)) \right) = |\beta_{ab}\rangle \otimes \mathsf{Z}^{a'} \mathsf{X}^{b'} \left(U(\mathsf{X}^b \mathsf{Z}^a(|\phi\rangle)) \right)$$
$$= |\beta_{ab}\rangle \otimes \mathsf{Z}^{a'} \mathsf{X}^{b'} \left(\mathsf{X}^{b'} \mathsf{Z}^{a'} U(|\psi\rangle) \right) = |\beta_{ab}\rangle \otimes U(|\psi\rangle)$$

7. Trace out the state $|\beta_{ab}\rangle$ from the above system and obtained the state $U(|\psi\rangle)$

$$U(|\psi\rangle) = Tr_{|\beta_{ab}\rangle} (|\beta_{ab}\rangle \otimes U(|\psi\rangle))$$

Remark. Using gate teleportation we can also evaluate a T, however, the correction function becomes more complicated.

$$\mathsf{T}\mathsf{X}^b\mathsf{Z}^a=\mathsf{X}^b\mathsf{Z}^{a\oplus b}\mathsf{P}^b\mathsf{T}$$

3 Quantum Indistinguishability Obfuscation

3.1 Definitions

Definition 3. (Equivalent Quantum Circuits): Let C_{q_0} and C_{q_1} be two n-qubit quantum circuits. We say C_{q_0} and C_{q_1} are equivalent if for every state $|\psi\rangle \in Q(n)$

$$C_{q_1}(|\psi\rangle) = C_{q_2}(|\psi\rangle).$$

Definition 4. (Quantum Indistinguishability Obfuscation) A polynomial-time quantum algorithm for a class of quantum circuits C_Q is a quantum (computational) indistinguishability obfuscator $Qi\mathcal{O}$ if the following conditions hold:

1. Functionality: For every $C_q \in \mathcal{C}_Q$ and every quantum state $|\phi\rangle$,

$$(\rho, C_q') \leftarrow Qi\mathcal{O}(C_q) \text{ and } C_q'(\rho, |\phi\rangle) = C_q(|\phi\rangle)$$

- 2. Polynomial Slowdown: For every $C_q \in \mathcal{C}_Q,$
 - $\rho \in Qubit(poly(|C_q|))$, i.e. ρ is at most a $poly(|C_q|)$ qubit state.
 - $|C'_q| \in poly(|C_q|)$.
- 3. Indistinguishability: For any two equivalent quantum circuits $C_{q_1}, C_{q_2} \in C_Q$, of the same size and for every polynomial-time quantum distinguisher \mathcal{D}_q , there exists a negligible function negl such that:

$$\left|\Pr[\mathcal{D}_q(Qi\mathcal{O}(C_{q_1}))=1] - \Pr[\mathcal{D}_q(Qi\mathcal{O}(C_{q_2}))=1]\right| \leq \operatorname{negl}(k).$$
 Where $k=|C_{q_1}|=|C_{q_2}|.$

3.2 Quantum Indistinguishability Obfuscation for Clifford Circuits

In this section we present two methods to obfuscate any Clifford circuit, one using a canonical form and the other using the gate teleportation.

3.2.1 Quantum Indistinguishability Obfuscation using Canonical Form

Aronson and Gottesman invented a polynomial-time algorithm that computed a canonical form of any Clifford circuit [?]. Their algorithm (we denote as AG-Canonical, page 8 - 9 [?]) takes a tableau (binary matrix) related to a Clifford circuit as an input and output its canonical form. However, the AG-Canonical lacks two properties that our important for obtaining $Qi\mathcal{O}$. First, it does not take a circuit as an input, but rather a $2n \times 2n$ binary matrix representing some quantum state and second, the canonical form computed by it may not always be unique. In this section we

show that how one can easily tweak AG-Canonical, so that it satisfies both of the properties and allow us to construct a $Qi\mathcal{O}$ for all Clifford Circuits. We start by briefly describing AG-Canonical.

The algorithm represent an *n*-qubit state by tableau consist of 2n rows and 2n + 1 columns, where $x_{i,j}, z_{i,j} \in \{0, 1\}$.

$$\begin{pmatrix} z_{11} & \cdots & z_{1n} & x_{11} & \cdots & x_{1n} & r_1 \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \vdots \\ z_{n1} & \cdots & z_{nn} & x_{n1} & \cdots & x_{nn} & r_n \\ \hline z_{(n+1)1} & \cdots & z_{(n+1)n} & x_{(n+1)1} & \cdots & x_{(n+1)n} & r_{n+1} \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \vdots \\ z_{(2n)1} & \cdots & z_{(2n)n} & x_{(2n)1} & \cdots & x_{(2n)n} & r_{2n} \end{pmatrix}$$

Each row of the tableau $R_i = \pm (P_1 \otimes \cdots \otimes P_n) \in \mathcal{P}_n$, for $1 \leq i \leq 2n$, where bits (x_{ij}, z_{ij}) determine the j^{th} Pauli gate P_j : 00 means I, 01 means X, 11 means Y, and 10 means Z and r_i is 1 if R_i has negative phase and 0 if r_i has positive phase. Rows 1 to n of the tableau represent the destabilizer generators R_1, \ldots, R_n and rows n+1 to 2n represent the stabilizer generators R_{n+1}, \ldots, R_{2n} of the state it represents. A state is uniquely determined by the group of pauli operators that stabilize it.

For example for the 2-qubit state $|00\rangle$ a possible tableau is

$$\left(\begin{array}{ccc|cccc}
1 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
\hline
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 & 0
\end{array}\right)$$

and the stabilizer generator for the state are $R_3 = +(\mathsf{Z} \otimes \mathsf{I})$ and $R_4 = +(\mathsf{I} \otimes \mathsf{Z})$. Note if we swap row 3 with row 4, then we get another tableau for the state $|00\rangle$, therefore a quantum state can be represented by more than one tableau. Now suppose we want to compute a canonical form of an n-qubit Clifford circuit C_q . Let \mathcal{T}_i be a initial tableau representing the state $|0\rangle^{\otimes n}$. As we proceeds through the gates in C_q ; we update \mathcal{T}_i according to the following rules [?].

CNOT from control a to target b. For all $i \in \{1, ..., 2n\}$, set $r_i := r_i \oplus x_{ia}z_{ib}$ $(x_{ib} \oplus z_{ia} \oplus 1)$, $x_{ib} := x_{ib} \oplus x_{ia}$, and $z_{ia} := z_{ia} \oplus z_{ib}$.

Hadamard on qubit a. For all $i \in \{1, ..., 2n\}$, set $r_i := r_i \oplus x_{ia} z_{ia}$ and swap x_{ia} with z_{ia} .

Phase on qubit a. For all $i \in \{1, ..., 2n\}$, set $r_i := r_i \oplus x_{ia}z_{ia}$ and then set $z_{ia} := z_{ia} \oplus x_{ia}$.

Let \mathcal{T}_f be the final tableau representing the state $C_q(|0\rangle^{\otimes n})$. The algorithm AG-Canonical takes the $2n \times 2n$ entries of \mathcal{T}_f (ignore the phase bits r_i) as a input and compute a canonical form as follows: First write the tableau into four $n \times n$ matrices A, B, C and D

$$\begin{bmatrix}
A & B \\
C & D
\end{bmatrix}$$

apply 11 rounds $\mathsf{H}-\mathsf{CNOT}-\mathsf{P}-\mathsf{CNOT}-\mathsf{P}-\mathsf{CNOT}-\mathsf{P}-\mathsf{CNOT}-\mathsf{P}-\mathsf{CNOT}-\mathsf{P}-\mathsf{CNOT}$ to the above block matrix to obtain standard initial tableau $[\mathbf{I}_{2n}|\mathbf{0}]$. Let $(g_i)_{i=1}^k$, $k\in\mathbb{N}$ be the sequence of gates corresponding to these rounds. Then the canonical form of the circuit C_q is given be the reverse of the sequence $(g_i)_{i=1}^k$. Now suppose C_q' is another circuit that is equivalent to C_q and $\mathcal{T}_i'\neq\mathcal{T}_i$ be a initial tableau representing the state $|0\rangle^{\otimes n}$. Let \mathcal{T}_f' be the final tableau representing the state $C_q'(|0\rangle^{\otimes n})$. Then it is possible that $\mathcal{T}_f\neq\mathcal{T}_f'$ and in this case the sequence $(g_i')_{i=1}^{k'}\leftarrow \mathsf{AG}-\mathsf{Canonical}(\mathcal{T}_f')$ is different from $(g_i)_{i=1}^k$, $k\in\mathbb{N}$. Therefore, in general the output of $\mathsf{AG}-\mathsf{Canonical}$ can be different for two equivalent circuits.

However, one can trivially modified the algorithm (AG-Canonical) [?] so that it take a Clifford circuit as an input and outputs a unique canonical form. We add the following initial lines of code to AG-Canonical and called this new algorithm AG-Canonical-Unique.

(AG-Canonical-Unique)

Input: A n-qubit Clifford Circuit C_q .

- 1. Set $\mathcal{T}_i = [\mathbf{I}_{2n} | \mathbf{0}] \in \{0, 1\}^{2n \times 2n + 1}$ be the standard initial tableau representing the state $|0\rangle^{\otimes n}$.
- 2. Compute the final tableau \mathcal{T}_f by running \mathcal{T}_i on C_q .
- 3. Computes the circuit $C_q' \leftarrow \texttt{AG-Canonical}(\mathcal{T}_f)$.
- 4. Output C'_a .

Lemma 3.1. The AG-Canonical-Unique computes a unique canonical form for Clifford Circuits in polynomial-time.

Proof. The cost of computing the final tableau \mathcal{T}_f is at most O(n) gates ([?]) and $|C'_q| \in O(poly(|n|))$ ([?]). Note, for any n-qubit circuit $n \leq |C_q|$, therefore the size of the algorithm AG-Canonical-Unique is at most $poly(|C_q|)$ gates. Moreover, Aronson and Gottesman proved in [?] that if C_{q_1} and C_{q_2} are two Clifford circuits and \mathcal{T}_{f_1} and \mathcal{T}_{f_2} are their final tableaus obtained by running them on the standard initial tableau $\mathcal{T}_{i_1} = \mathcal{T}_{i_2} = [\mathbf{I}_{2n}|\mathbf{0}]$, then C_{q_1} and C_{q_2} are equivalent if and only if $\mathcal{T}_{f_1} = \mathcal{T}_{f_2}$. This means the final tableau \mathcal{T}_f obtain in AG-Canonical-Unique is the same for every equivalent Clifford circuit. Therefore AG-Canonical-Unique computes a unique canonical form for Clifford circuits.

Quantum Indistinguishability Obfuscator from Canonical Form: On input a Clifford circuit C_q , the $Qi\mathcal{O}$ first computes the canonical form AG-Canonical-Unique (C_q) and then outputs an empty register ρ along with AG-Canonical-Unique (C_q) .

$$(\rho, \texttt{AG-Canonical-Unique}(C_q)) \leftarrow Qi\mathcal{O}(C_q).$$

Note we output an empty register ρ to be consistent with our definition of $Qi\mathcal{O}$. Clearly, $Qi\mathcal{O}$ satisfy the first two properties (functionality and polynomial slow down). Moreover the canonical form reveals no knowledge about the input circuit, therefore this $Qi\mathcal{O}$ is perfectly indistinguishable against any quantum adversary.

3.2.2 Quantum Indistinguishability Obfuscation using Gate Teleportation

In this section we will show that how gate teleportation can be used to obfuscate Clifford circuits. Our algorithm relies on the assumption that there exists a quantum secure $i\mathcal{O}$ for classical circuits, this seems problematic at first since, there is no provably quantum secure $i\mathcal{O}$ known for general classical circuits. However, our construction relies on the assumption that a quantum secure $i\mathcal{O}$ exists for a very specific class of circuits that are associated with the update functions (section 2.3). In fact, to construct a quantum secure $i\mathcal{O}$ for the family circuits (update functions) corresponding to Clifford circuits is quite easy (section 3.3).

Algorithm 2 $Qi\mathcal{O}$ using Gate Teleportation

- Input: A *n*-qubit Clifford Circuit C_q .
 - 1. Prepare 2n qubit Bell state $|\beta^{2n}\rangle = |\beta_{00}\rangle \otimes \cdots \otimes |\beta_{00}\rangle$.
 - 2. Apply the circuit C_q on the lower half of the qubits $|\rho\rangle = (I \otimes C_q)|\beta^{2n}\rangle$.
 - 3. Compute the circuit C'_q (define below).
 - 4. Output $(|\rho\rangle, C'_q)$.

Algorithm 3 Circuit C'_q

- Input $(|\rho\rangle, |\psi\rangle)$
 - 1. Measure the first 2n qubits of the system $|\rho\rangle \otimes |\psi\rangle$ in the Bell basis and obtain the classical output (a_1,b_1,\ldots,a_n,b_n) . (Note last n-qubits are now in the state $C_q(\mathsf{X}^{\otimes_{i=1}^n b_i} \cdot \mathsf{Z}^{\otimes_{i=1}^n a_i})(|\phi\rangle) = (\mathsf{X}^{\otimes_{i=1}^n b_i'} \cdot \mathsf{Z}^{\otimes_{i=1}^n a_i'})C_q(|\phi\rangle)$ see section 2.4).
 - 2. Compute the correction bits $(a'_1, b'_1, \ldots, a'_n, b'_n) = i\mathcal{O}(C_{F_{C_q}})(a_1, b_1, \ldots, a_n, b_n)$. Where $C_{F_{C_q}}$ is the circuit that computes F_{C_q} .
 - 3. Apply $(\mathsf{X}^{\otimes_{i=1}^n b_i'} \cdot \mathsf{Z}^{\otimes_{i=1}^n a_i'})$ to the system $C_q(\mathsf{X}^{\otimes_{i=1}^n b_i} \cdot \mathsf{Z}^{\otimes_{i=1}^n a_i})(|\phi\rangle)$ and output the state $C_q(|\phi\rangle)$.

Theorem 3.2. If $i\mathcal{O}$ is a quantum secure classical indistinguishability obfuscation, then $Qi\mathcal{O}$ constructed from the gate teleportation protocol is a quantum Indistinguishability Obfuscation for all Clifford Circuits.

Proof:

- Functionality: The functionality $Qi\mathcal{O}$ is followed from the gate teleportation.
- Polynomial Slowdown: Note ρ is a 2n-qubit state and the size of C'_q is equal to the size of the circuits that computes the Bell measurement, $i\mathcal{O}(F_{C_q})$ and $(\mathsf{X}^{\otimes_{i=1}^n b'_i} \cdot \mathsf{Z}^{\otimes_{i=1}^n a'_i})$. The Bell measurement of an O(n) qubit system can be perform by a circuit of size O(n) and clearly the size of the circuit $(\mathsf{X}^{\otimes_{i=1}^n b'_i} \cdot \mathsf{Z}^{\otimes_{i=1}^n a'_i})$ is in O(n). The function F_{C_q} takes 2n bits as an input and perform \mathbf{XOR} or \mathbf{Swap} operations on it as its passes through each layer of the gates in C_q . There are at most $|C_q|$ layers of gates, therefore the total number gates required to compute F_{C_q} is $poly(n)|C_q|$. Since, for any n-qubit circuit C_q , $n \leq |C_q|$, the function F_{C_q} can be computed by a circuit of size at most $poly(|C_q|)$. Hence, the size of $|C'_q| \in poly(|C_q|)$.
- Indistinguishability: Let C_{q_1} and C_{q_2} be two n-qubit equivalent Clifford circuits

$$(|\rho_1\rangle, C'_{q_1}) = Qi\mathcal{O}(C_{q_1})$$
 and $(|\rho_2\rangle, C'_{q_2}) = Qi\mathcal{O}(C_{q_2})$

Since $C_{q_1}(|\tau\rangle)=C_{q_2}(|\tau\rangle)$ for every quantum state $|\tau\rangle$ we have,

$$|\rho_1\rangle = (I \otimes C_{q_1})|\beta^{2n}\rangle = (I \otimes C_{q_2})|\beta^{2n}\rangle = |\rho_2\rangle.$$

so the first part of the $Qi\mathcal{O}$ output is perfectly indistinguishable. Now for the second part note that he only difference between C'_{q_1} and C'_{q_2} are circuits that compute the update functions $F_{C_{q_1}}$ and $F_{C_{q_2}}$. If we can prove that $F_{C_{q_1}}(\mathbf{s}) = F_{C_{q_2}}(\mathbf{s})$ for every $\mathbf{s} \in \{0,1\}^{2n}$, then from definition of classical indistinguishability obfuscation we can conclude that $i\mathcal{O}(C_{F_{C_{q_2}}})$ and $i\mathcal{O}(C_{F_{C_{q_2}}})$ are computationally indistinguishable against any quantum adversary ³

From Theorem 3.3 we have $F_{C_{q_1}}$ and $F_{C_{q_2}}$ equivalent functions, therefore $Qi\mathcal{O}$ is a quantum indistinguishability obfuscation for all Clifford Circuits.

Theorem 3.3. Let C_{q_1} and C_{q_2} be two equivalent Clifford circuits and $F_{C_{q_1}}$ and $F_{C_{q_2}}$ denote the update functions for the circuits C_{q_1} and C_{q_2} , then $F_{C_{q_1}}(\mathbf{s}) = F_{C_{q_2}}(\mathbf{s})$ for every $\mathbf{s} \in \{0,1\}^{2n}$.

Proof: For any *n*-qubit state $|\psi\rangle$ we have $C_{q_1}(|\psi\rangle) = C_{q_2}(|\psi\rangle)$. If we use Circuit teleportation protocol to compute $C_1(|\psi\rangle)$ and $C_{q_2}(|\psi\rangle)$, After measurement and tracing out the bell states the system corresponding to the circuit C_{q_1} and C_{q_2} are in the states.

$$C_{q_1}(\mathbf{U}|\psi\rangle) = \mathbf{U}_{C_{q_1}}C_{q_1}(|\psi\rangle) \text{ and } C_{q_2}(\mathbf{U}|\psi\rangle) = \mathbf{U}_{C_{q_2}}(C_{q_2}(|\psi\rangle))$$

Where

$$U = (X^{\bigotimes_{i=1}^{n} b_i} \cdot Z^{\bigotimes_{i=1}^{n} a_i}),$$

³Note without loss of generality we can assume that $|C_{F_{C_{q_1}}}| = |C_{F_{C_{q_2}}}|$, because we can always increase the size of a circuit by adding trivial gates to it.

$$U_{C_{q_1}} = (X^{\bigotimes_{i=1}^n b'_i} \cdot Z^{\bigotimes_{i=1}^n a'_i}),$$

$$U_{C_{q_2}} = (X^{\bigotimes_{i=1}^n e'_i} \cdot Z^{\bigotimes_{i=1}^n d'_i}).$$

 $F_{C_{q_1}}(a_1, b_1, \dots, a_n, b_n) = (a'_1, b'_1, \dots, a'_n, b'_n)$ and $F_{C_{q_2}}(d_1, e_1, \dots, d_n, e_n) = (d'_1, e'_1, \dots, d'_n, e'_n)$

We have

$$\begin{split} C_{q_1}(|\psi\rangle) &= (\mathbf{U}_{C_{q_1}}^{\dagger} \mathbf{U}_{C_{q_1}}) C_{q_1}(|\psi\rangle) = \mathbf{U}_{C_{q_1}}^{\dagger} (C_{q_1}(\mathbf{U}(|\psi\rangle)) \\ &= \mathbf{U}_{C_{q_1}}^{\dagger} (C_{q_2}(\mathbf{U}(|\psi\rangle)), [C_{q_1} \text{ and } C_{q_2} \text{ are equivalent }] \\ &= \mathbf{U}_{C_{q_1}}^{\dagger} \mathbf{U}_{C_{q_2}} (C_{q_2}(|\psi\rangle)) = C_{q_2}(|\psi\rangle) \\ &\Longrightarrow \mathbf{U}_{C_{q_1}}^{\dagger} \mathbf{U}_{C_{q_2}} = \mathbf{I} \Longleftrightarrow \mathbf{U}_{C_{q_1}} = \mathbf{U}_{C_{q_2}} \end{split}$$

By Lemma 3.4 we have that $F_{C_{q_1}} = F_{C_{q_2}}$.

Lemma 3.4. Let C_{q_1} and C_{q_2} be two equivalent Clifford circuits, then $F_{C_{q_1}} = F_{C_{q_2}}$ if and only if $U_{C_{q_1}} = U_{C_{q_2}}$.

Proof: $(p \Rightarrow q)$ Suppose $F_{C_{q_1}} = F_{C_{q_2}}$ then clearly $U_{C_{q_1}} = U_{C_{q_2}}$.

Now to proof $(q \Rightarrow p)$ Suppose $U_{C_{q_1}} = U_{C_{q_2}}$ and $F_{C_{q_1}} \neq F_{C_{q_2}}$, then there exists a binary string $(a_1, b_1, \ldots, a_n, b_n)$ such that

$$F_{C_{q_1}}(a_1, b_1, \dots, a_n, b_n) \neq F_{C_{q_2}}(a_1, b_1, \dots, a_n, b_n)$$

Since $U_{C_{q_1}}(|\psi\rangle) = U_{C_{q_2}}(|\psi\rangle)$ for every *n*-qubit state $|\psi\rangle$. Let

$$|\psi\rangle = |\phi_1\rangle \otimes |\phi_2\rangle \otimes \cdots \otimes |\phi_n\rangle$$

where $|\phi_i\rangle = \alpha_i |0\rangle + \beta_i |1\rangle$, $\alpha_i \neq 0$ and $\beta_i \neq 0$, for every integer $1 \leq i \leq n$.

$$U_{C_{q_1}}(|\psi\rangle) = \left(\alpha_1|0 + a_1'\rangle + (-1)^{b_1'}(i)^{c_1'}\beta_1|1\rangle\right) \otimes \cdots \otimes \left(\alpha_n|0 + a_n'\rangle + (-1)^{b_n'}(i)^{c_1'}\beta_n|1\rangle\right)$$

$$U_{C_{q_2}}(|\psi\rangle) = \left(\alpha_1|0+d_1'\rangle + (-1)^{e_1'}(i)^{f_1'}\beta_1|1\rangle\right) \otimes \cdots \otimes \left(\alpha_n|0+d_n'\rangle + (-1)^{e_n'}(i)^{f_1'}\beta_n|1\rangle\right)$$

For any i if $a'_i \neq d'_i$ or $b'_i \neq e'_i$ or $c'_i \neq f'_i$ then the output $U_{C_{q_1}}(|\psi\rangle)$ will differ from $U_{C_{q_2}}(|\psi\rangle)$ on the i-th qubit. Which is a contraction to the assumption that $U_{C_{q_1}} = U_{C_{q_2}}$. Therefore $F_{C_{q_1}} = F_{C_{q_2}}$.

3.3 Indistinguishability Obfuscation for the Clifford Update Functions

In this section we present a (quantum secure classical) $i\mathcal{O}$ that can obfuscate the update function F_{C_q} , for any n-qubit Clifford circuit C_q .

Algorithm 4 $i\mathcal{O}$ for Clifford update Functions $F_{\texttt{Clifford}}$

- Input: A *n*-qubit Clifford Circuit C_q , a security parameter.
 - 1. Compute $C_{q_c} \leftarrow \texttt{AG-Canonical-Unique}(C_q)$.
 - 2. Compute the circuit $C_{F_{q_c}}$ for the update function $F_{C_{q_c}}$.
 - 3. Output $C_{F_{q_c}}$.

4 Obfuscating Beyond Clifford Circuits

Here, we show how to build iO for quantum circuit families that satisfy Definition 2.

4.0.1 Using a Canonical Form

Main idea: Each Clifford layer is obfuscated using the canonical form. The T gate layers are given in the clear. The result is a canonical form, since the family is selected such that the description just given will be a canonical form.

4.0.2 Using Gate Teleportation

As mentioned in the section 2 that adding a non-Clifford gates such as T to Clifford gates gives us a generating set for all quantum circuits. The T relates to the X,Z

$$\mathsf{T}\mathsf{X}^b\mathsf{Z}^a=\mathsf{X}^b\mathsf{Z}^{a\oplus b}\mathsf{P}^b\mathsf{T}$$

Note we write $P = (\frac{1+i}{2})I + (\frac{1-i}{2})Z$,

$$\mathsf{T}\mathsf{X}^b\mathsf{Z}^a = \mathsf{X}^b\mathsf{Z}^{a\oplus b}\left[\left(\frac{1+i}{2})\mathsf{I} + (\frac{1-i}{2}\right)\mathsf{Z}\right]^b\mathsf{T}$$

$$\mathsf{T}\mathsf{X}^b\mathsf{Z}^a = \mathsf{X}^b\mathsf{Z}^{a\oplus b}\left[\left(\frac{1+i}{2}\right)\mathsf{I} + \left(\frac{1-i}{2}\right)\mathsf{Z}^b\right]\mathsf{T}$$

Now suppose we want evaluate the circuit HT on some qubit $|\phi\rangle$ using gate teleportation, then

$$\mathsf{HTX}^b\mathsf{Z}^a(|\phi\rangle)=\mathsf{X}^{b\oplus a}\mathsf{Z}^b\mathsf{HP}^b\mathsf{T}(|\phi\rangle)$$

If b = 0, then we don't have to worry about P correction, otherwise we have to perform a P correction which is a problem since H and P does not compute.

$$\begin{split} \mathsf{HTX}^b \mathsf{Z}^a(|\phi\rangle &= \mathsf{X}^{a \oplus b} \mathsf{Z}^b \left[\left(\frac{1+i}{2} \right) \mathsf{H} + \left(\frac{1-i}{2} \right) \mathsf{HZ}^b \right] \mathsf{T}(|\phi\rangle) \\ &= \mathsf{X}^{a \oplus b} \mathsf{Z}^b \left[\left(\frac{1+i}{2} \right) \mathsf{I} + \left(\frac{1-i}{2} \right) \mathsf{X}^b \right] \mathsf{HT}(|\phi\rangle) \\ &= \left[\left(\frac{1+i}{2} \right) \mathsf{X}^{a \oplus b} \mathsf{Z}^b + (-1)^b \left(\frac{1-i}{2} \right) \mathsf{X}^a \mathsf{Z}^b \right] \mathsf{HT}(|\phi\rangle) \\ &= \left[\alpha_1 \mathsf{X}^{a \oplus b} \mathsf{Z}^b + (-1)^b \alpha_2 \mathsf{X}^a \mathsf{Z}^b \right] \mathsf{HT}(|\phi\rangle) \end{split}$$

where $\alpha_1 = \left(\frac{1+i}{2}\right)$ and $\alpha_2 = \left(\frac{1-i}{2}\right)$. For this particular circuit the update function required at most two complex numbers and four bits. In general for any 1-qubit unitary circuit we need to store at most fours complex numbers and eights bits to represent the corresponding update function. To realize this note that the set $\{H,T\}$ is universal for 1-qubit unitary and any 1-qubit (unitary circuit) can be written as an alternating sequence of H, and T as follows,

$$C_q = \mathsf{G} - \mathsf{T} - \mathsf{H} - \mathsf{T} - \mathsf{H} - \cdots - \mathsf{T} - \mathsf{H} - \mathsf{T} - \mathsf{G}$$

where G = H or G = I.

Lets compute this circuit gate by gate on some qubit $|\phi\rangle$ using gate teleportation

1)
$$\mathsf{GX}^b\mathsf{Z}^a(|\phi\rangle) = \mathsf{X}^{b_1}\mathsf{Z}^{a_1}\mathsf{G}(|\phi\rangle)$$
, where $b_1 = a, \ a_1 = b, \ \text{if } \mathsf{G} = \mathsf{H}, \ \text{otherwise} \ b_1 = b, \ a_1 = a.$

2)
$$\mathsf{TX}^{b_1}\mathsf{Z}^{a_1}\mathsf{G} = (\alpha_1\mathsf{X}^{a_1\oplus b_1}\mathsf{Z}^{b_1} + (-1)^{b_1}\alpha_2\mathsf{X}^{a_1}\mathsf{Z}^{b_1})\mathsf{TG}.$$

$$3) \ \ \mathsf{H}(\alpha_1 \mathsf{X}^{a_1 \oplus b_1} \mathsf{Z}^{b_1} + (-1)^{b_1} \alpha_2 \alpha_2 \mathsf{X}^{a_1} \mathsf{Z}^{b_1}) \mathsf{TG} = (\alpha_1 \mathsf{X}^{b_1} \mathsf{Z}^{a_1 \oplus b_1} + (-1)^{b_1} \alpha_2 \mathsf{X}^{b_1} \mathsf{Z}^{a_1}) \mathsf{HTG}.$$

4)
$$\mathsf{T}(\alpha_1\mathsf{X}^{b_1}\mathsf{Z}^{a_1\oplus b_1} + \alpha_2\mathsf{X}^{b_1}\mathsf{Z}^{a_1})\mathsf{HTG} = \left(\frac{i}{2}\mathsf{X}^{a_1}\mathsf{Z}^{a_1\oplus b_1} + \frac{(-1)^{b_1}}{2}\mathsf{X}^{a_1\oplus b_1}\mathsf{Z}^{b_1} + \frac{(-1)^{b_1}}{2}\mathsf{X}^{a_1\oplus b_1}\mathsf{Z}^{a_1} - \frac{i}{2}\mathsf{X}^{a_1}\mathsf{Z}^{b_1}\right)\mathsf{THTG}.$$

5)
$$\mathsf{H}\left(\frac{i}{2}\mathsf{X}^{a_1}\mathsf{Z}^{a_1\oplus b_1} + \frac{(-1)^{b_1}}{2}\mathsf{X}^{a_1\oplus b_1}\mathsf{Z}^{b_1} + \frac{(-1)^{b_1}}{2}\mathsf{X}^{a_1\oplus b_1}\mathsf{Z}^{a_1} - \frac{i}{2}\mathsf{X}^{a_1}\mathsf{Z}^{b_1}\right)\mathsf{THTG}$$

$$= \left(\frac{i}{2}\mathsf{X}^{a_1\oplus b_1}\mathsf{Z}^{a_1} + \frac{(-1)^{b_1}}{2}\mathsf{X}^{b_1}\mathsf{Z}^{a_1\oplus b_1} + \frac{(-1)^{b_1}}{2}\mathsf{X}^{a_1}\mathsf{Z}^{a_1\oplus b_1} - \frac{i}{2}\mathsf{X}^{b_1}\mathsf{Z}^{a_1}\right)\mathsf{HTHTG}$$

$$= (c_1\mathsf{I} + c_2\mathsf{X} + c_3\mathsf{Z} + c_4\mathsf{XZ})\mathsf{HTHTG}, \text{ for } c_i \in \mathbb{C}.$$

6)
$$\begin{split} \mathsf{T}\left(c_1\mathsf{I} + c_2\mathsf{X} + c_3\mathsf{Z} + c_4\mathsf{XZ}\right)\mathsf{HTHTG} &= \left(c_1\mathsf{I} + c_2\mathsf{XZP} + c_3\mathsf{Z} + c_4\mathsf{XP}\right)\mathsf{TXZHTHTG} \\ &= \left(c_1\mathsf{I} + c_2'\mathsf{X} + c_3\mathsf{Z} + c_4'\mathsf{XZ}\right)\mathsf{TXZHTHTG}, \\ \text{where } c_2' &= \left(c_2\alpha_2 + c_4\alpha_1\right) \text{ and } c_4' &= \left(c_2\alpha_1 + c_4\alpha_2\right). \end{split}$$

- Note applying T gate in the line 6 only affected the coefficients but didn't increase the number of terms in the summation. It is easy to see that after applying the remain gates in C_q we will have the quantity

$$(\beta_1 \mathsf{I} + \beta_2 \mathsf{X} + \beta_3 \mathsf{Z} + \beta_4 \mathsf{XZ}) C_q(|\phi\rangle), \text{ where } \beta_i \in \mathbb{C}.$$

Further more the correction matrix $(\beta_1 I + \beta_2 X + \beta_3 Z + \beta_4 X Z)^{-1}$ is completely determine by $(\beta_1, \beta_2, \beta_3, \beta_4)$. Therefore, for any arbitrary 1-qubit unitary circuit C_q , the update function is

$$F_{C_a}: \mathbb{F}_2^2 \longrightarrow \mathbb{C}^4, \quad (a,b) \longrightarrow (\beta_1, \beta_2, \beta_3, \beta_4).$$

How big are the $\beta_i's$? Note each $\beta_i's$ are generated by multiplying and adding elements from the set $\{\left(\frac{1+i}{2}\right),\left(\frac{1-i}{2}\right)\}$. Moreover, $\left(\frac{1\pm i}{2}\right)^k=\pm\frac{i}{2}$ and $\left(\frac{1+i}{2}\right)\left(\frac{1-i}{2}\right)=\frac{1}{2}$ and only T can have impact on the size of the coefficients in the summation. Therefore, the size of complex numbers grows polynomially in the number of T gates. So we obfuscate any 1-qubit unitary circuit using gate teleportation protocol.

What about n-qubit circuits for n > 1? As we will see that if a circuit has k number of T gates, then in the worst-case the number of complex numbers required to specify grows super-polynomial in k. The problem arises when CNOT and T gates are mixed. To explain this let's consider the following 2-qubit circuit.

$$\mathsf{CNOT}_{2,1}(\mathsf{I} \otimes \mathsf{T})\mathsf{CNOT}_{1,2}(\mathsf{T} \otimes \mathsf{I})$$

Let compute this circuit gate by gate using gate-teleportation

1)
$$\mathsf{T}\otimes\mathsf{I}\left[\mathsf{X}^{b_1}\mathsf{Z}^{a_1}\otimes\mathsf{X}^{b_1'}\mathsf{Z}^{a_1'}\right]=\left[\alpha_1\mathsf{X}^{b_1}\mathsf{Z}^{a_1}\otimes\mathsf{X}^{b_1'}\mathsf{Z}^{a_1'\oplus b_1'}+\alpha_2\mathsf{X}^{b_1}\mathsf{Z}^{a_1}\otimes\mathsf{X}^{b_1'}\mathsf{Z}^{a_1'})\right]\mathsf{T}\otimes\mathsf{I}.$$

2)
$$\mathsf{CNOT}_{1,2} \left[\alpha_1 \mathsf{X}^{b_1} \mathsf{Z}^{a_1} \otimes \mathsf{X}^{b_1'} \mathsf{Z}^{a_1' \oplus b_1'} + \alpha_2 \mathsf{X}^{b_1} \mathsf{Z}^{a_1} \otimes \mathsf{X}^{b_1'} \mathsf{Z}^{a_1'} \right] (\mathsf{T} \otimes \mathsf{I})$$

$$= \left[(\alpha_1 \mathsf{X}^{b_1} \mathsf{Z}^{a_2} \otimes \mathsf{X}^{b_2} \mathsf{Z}^{a_1' \oplus b_1'} + \alpha_2 \mathsf{X}^{b_1} \mathsf{Z}^{a_2'} \otimes \mathsf{X}^{b_2'} \mathsf{Z}^{a_1'}) \right] \mathsf{CNOT}_{1,2} (\mathsf{T} \otimes \mathsf{I})$$
where $a_2 = a_1 \oplus a_1' \oplus b_1'$, $b_2 = b_1 \oplus b_1'$ and $a_2' = a_1 \oplus a_1'$, $b_2' = b_1 \oplus b_1'$.

3)
$$\mathbf{I} \otimes \mathbf{T} \left[\alpha_1 \mathbf{X}^{b_1} \mathbf{Z}^{a_2} \otimes \mathbf{X}^{b_2} \mathbf{Z}^{a'_1 \oplus b'_1} + \alpha_2 \mathbf{X}^{b_1} \mathbf{Z}^{a'_2} \otimes \mathbf{X}^{b'_2} \mathbf{Z}^{a'_1} \right] \mathsf{CNOT}_{1,2} (\mathsf{T} \otimes \mathsf{I}).$$

$$= \left[(\alpha_1^2 \mathbf{X}^{b_1} \mathbf{Z}^{a_2} \otimes \mathbf{X}^{b_2} \mathbf{Z}^{a'_1 \oplus b'_1}) + (\alpha_1 \alpha_2 \mathbf{X}^{b_1} \mathbf{Z}^{a_2 \oplus b_1} \otimes \mathbf{X}^{b_2} \mathbf{Z}^{a'_1 \oplus b'_1}) + (\alpha_1 \alpha_2 \mathbf{X}^{b_1} \mathbf{Z}^{a'_2} \otimes \mathbf{X}^{b'_2} \mathbf{Z}^{a'_1}) \right] + (\alpha_2^2 \mathbf{X}^{b_1} \mathbf{Z}^{a'_2 \oplus b_1} \otimes \mathbf{X}^{b'_2} \mathbf{Z}^{a'_1}) \right] (\mathsf{I} \otimes \mathsf{T}) \mathsf{CNOT}_{1,2} (\mathsf{T} \otimes \mathsf{I}).$$

4) Applying $CNOT_{2,1}$ to the above system.

$$\begin{split} &\left[(\alpha_1^2\mathsf{X}^{b_1\oplus b_2}\mathsf{Z}^{a_2}\otimes\mathsf{X}^{b_2}\mathsf{Z}^{a_1'\oplus b_1'}) + (\alpha_1\alpha_2\mathsf{X}^{b_1\oplus b_2}\mathsf{Z}^{a_2\oplus b_1}\otimes\mathsf{X}^{b_2}\mathsf{Z}^{a_1'\oplus b_1'}) + (\alpha_1\alpha_2\mathsf{X}^{b_1'}\mathsf{Z}^{a_2'}\otimes\mathsf{X}^{b_2'}\mathsf{Z}^{a_1}) + \\ &\left.(\alpha_2^2\mathsf{X}^{b_1'}\mathsf{Z}^{a_2'\oplus b_1}\otimes\mathsf{X}^{b_2}\mathsf{Z}^{a_1})\right]\mathsf{CNOT}_{2,1}(\mathsf{I}\otimes\mathsf{T})\mathsf{CNOT}_{1,2}(\mathsf{T}\otimes\mathsf{I}). \end{split}$$

$$= \left(\sum_{i=1}^4 \beta_i \mathsf{X}^{e_i} \mathsf{Z}^{d_i} \otimes \mathsf{X}^{e_i'} \mathsf{Z}^{d_i'}\right) \mathsf{CNOT}_{2,1}(\mathsf{I} \otimes \mathsf{T}) \mathsf{CNOT}_{1,2}(\mathsf{T} \otimes \mathsf{I}); \ \beta_i \in \mathbb{C}, e_i, d_i, e_i', d_i' \in \{0,1\}$$

We observe the following 2 things from the above example:

- 1) We need 4 complex numbers and 16 bits to represent the correction matrix.
- 2) CNOT gates when combine with T gates increases the number of terms in the expression.

For any 2-qubit quantum circuit C_q that has k number of T gates, the correction unitary in the worst-case has 2^k terms;

$$\sum_{i=1}^{2^k} \left(\beta_i \mathsf{X}^{e_i} \mathsf{Z}^{d_i} \otimes \mathsf{X}^{e_i'} \mathsf{Z}^{d_i'} \right), \text{ for } \beta_i \in \mathbb{C}, e_i, d_i, e_i', d_i' \in \{0, 1\}.$$

This means we need 2^k complex numbers and $2^k \cdot 4$ bits to represent the correction unitary and the update function $f_{C_q}: \mathbb{C}^{2^k} \times \{0,1\}^{2^{k+2}}$. Therefore, we can obfuscate any 2-qubit quantum circuit C_q using gate-teleportation as far as the number of T gates are at most $O(\log(|C_q|))$.

In, general, for any n-qubit circuit C_q , the correction unitary can be written as

$$\sum_{j=1}^{2^k} \left(\beta_j \mathsf{X}^{e_{1j}} \mathsf{Z}^{d_{1j}} \otimes \mathsf{X}^{e_{2j}} \mathsf{Z}^{d_{2j}} \otimes \cdots \otimes \mathsf{X}^{e_{2n}} \mathsf{Z}^{d_{2n}} \right),$$

where $\beta_i \in \mathbb{C}$ and $e_i, j, d_i, j \in \{0, 1\}$. This means we need 2^k complex numbers and $2^k \cdot n$ bits to represent the correction unitary and the update function $f_{C_q} : \{0, 1\}^n \longrightarrow \mathbb{C}^{2^k} \times \{0, 1\}^{n2^k}$.

5 Conclusion and Open Questions

The main open questions related to this work are:

 $i\mathcal{O}$ obfuscation for general quantum circuits

applications of gate-teleportation based quantum $i\mathcal{O}$ (for instance, to unclonable programs [?]).
